

ABSTRACT

In an implementation, a method includes forming a request by a client for communication to a licensing server. The request is for storing encrypted content by the client. A persistent license is received at the client in response to the request. The persistent license includes a key that is encrypted. The key, when decrypted, provides access to the encrypted content. The key is configured to be decrypted by the licensing server. The client, however, is not configured to decrypt the key from the persistent license. The persistent license and the encrypted content are stored by the client.
